#### Communication with Shared Secrets

We have several ways for Alice and Bob to send confidential messages, and all require a as a **shared secret** 

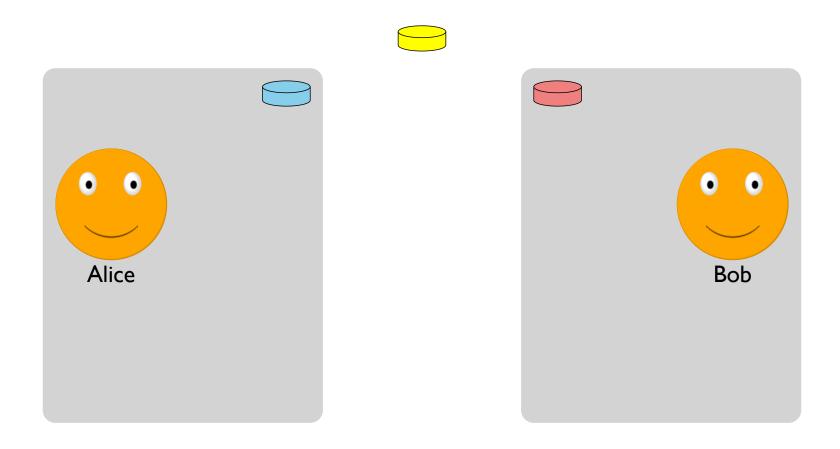

How do Alice and Bob get a shared secret in the first place?

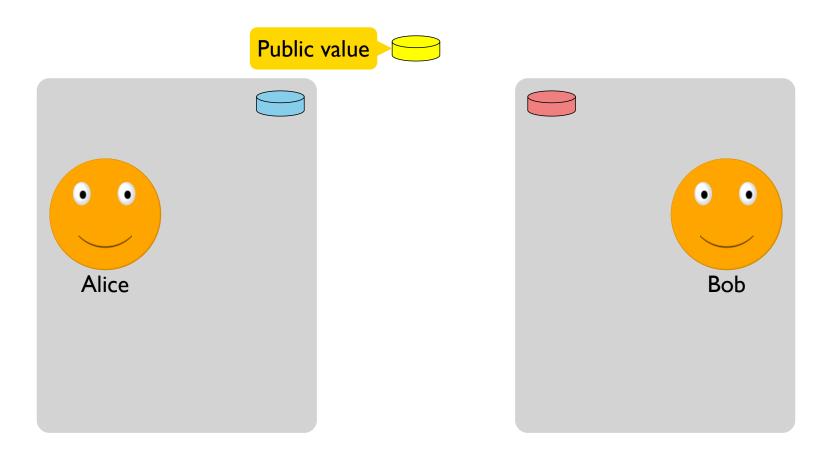

It turns out that it's possible to turn private secrets into a shared secret through a *public* conversation!

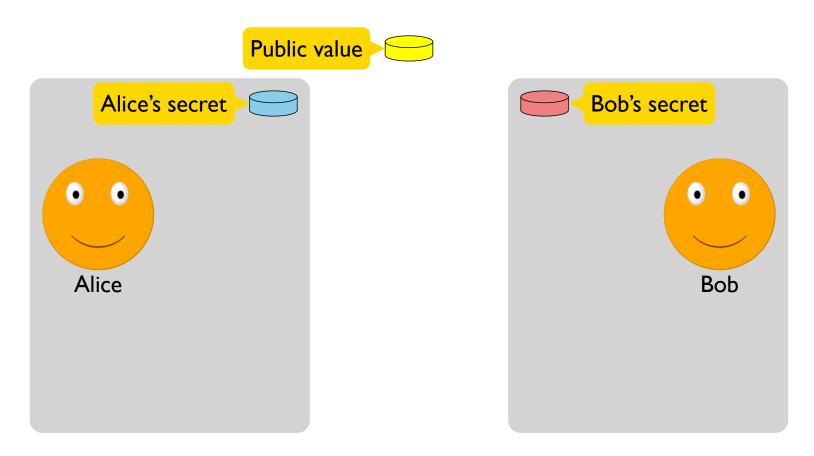

Two widely used algorithms to create shared secrets:

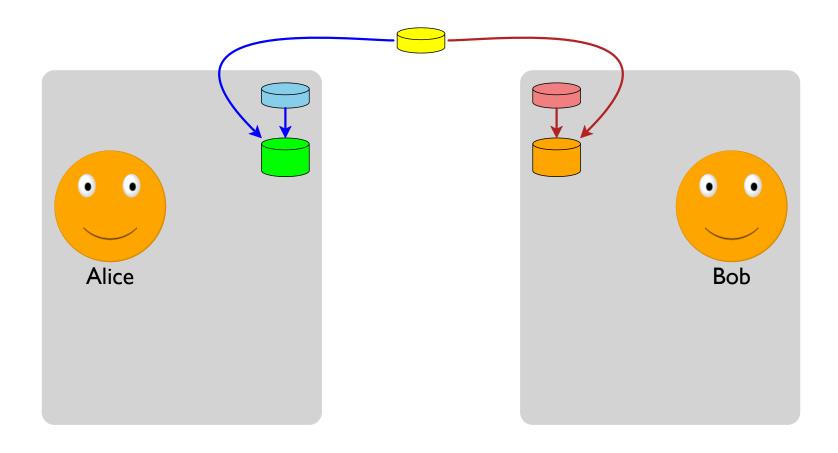

- Diffie-Hellman
- RSA

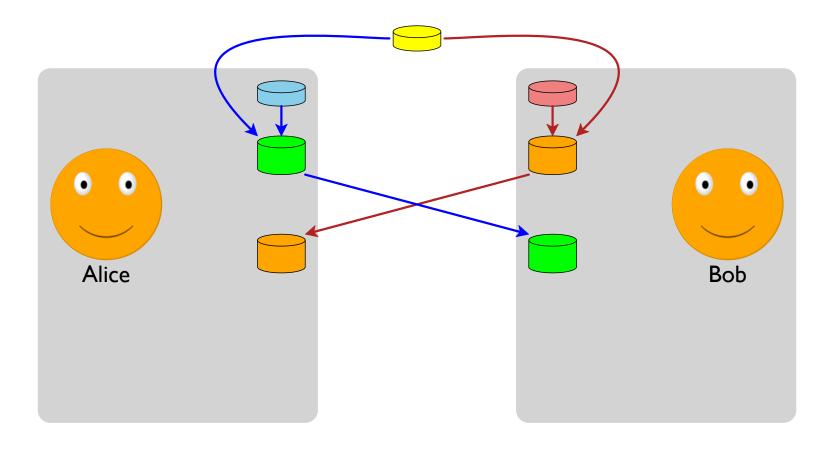

Both from the 1970s with similar capabilities—but different immediate uses, and RSA dominates for historical and commercial reasons

### Discrete Logarithm Problem

For a large p, a, and b, it's infeasible to get from

$$\mathbf{A} = \mathbf{g}^{\mathbf{a}} \mod \mathbf{p}$$

$$\mathbf{B} = \mathbf{g}^{\mathbf{b}} \bmod \mathbf{p}$$

back to a or b

"Large" in practice means 1024 to 8192 bits for p, a, and b

At that scale,  $g^a$ ,  $g^b$ , and  $g^{ab}$  do not remotely fit in in the universe, but the values mod p are small and can be computed quickly

#### Discrete Logarithm Problem

For a large p, a, and b, it's infeasible to get from

$$\mathbf{A} = \mathbf{g}^{\mathbf{a}} \mod \mathbf{p}$$

$$\mathbf{B} = \mathbf{g}^{\mathbf{b}} \bmod \mathbf{p}$$

back to a or b

"Large" in practice means 1024 to 8192 bits for p, a, and b

At that scale,  $g^a$ ,  $g^b$ , and  $g^{ab}$  do not remotely fit in in the universe, but the values mod p are small and can be computed quickly

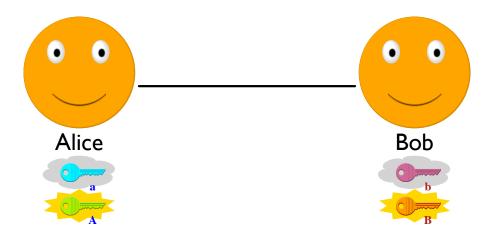

$$x^2 \mod p = (x \mod p)^2 \mod p$$
  
 $\Rightarrow$  divide and conquer

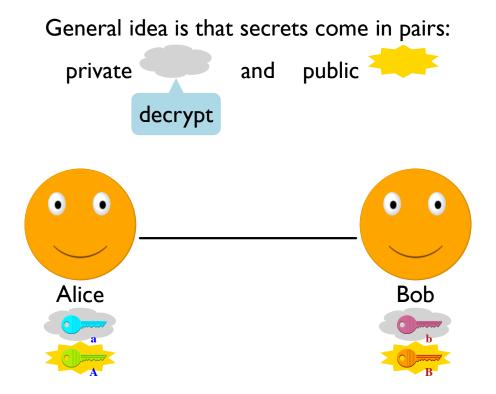

#### Internet Key Exchange (IKE)

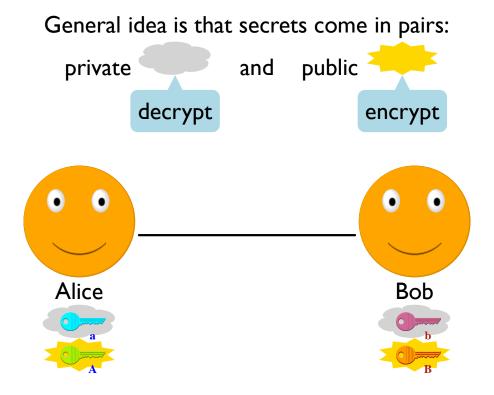

#### RFC 3526's 2048-bit **p** with g = 2:

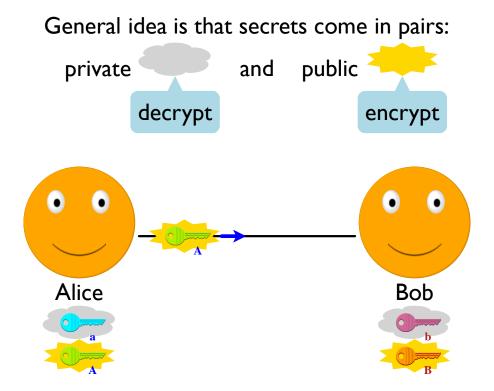

General idea is that secrets come in pairs:

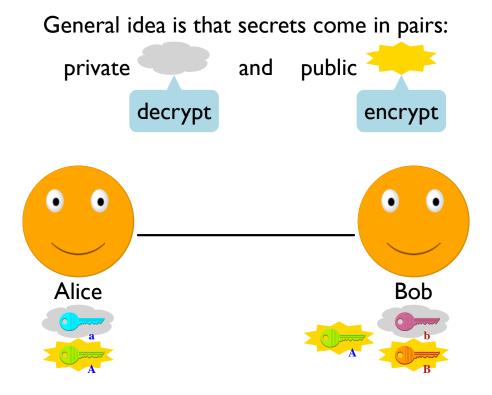

private and public

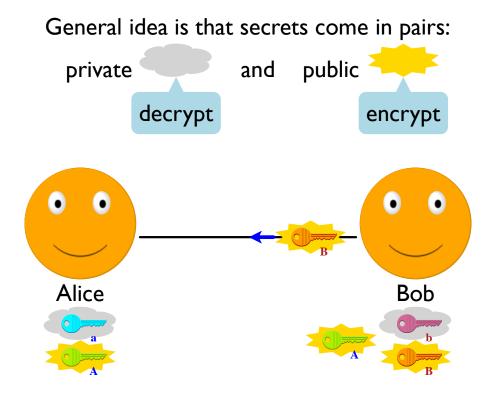

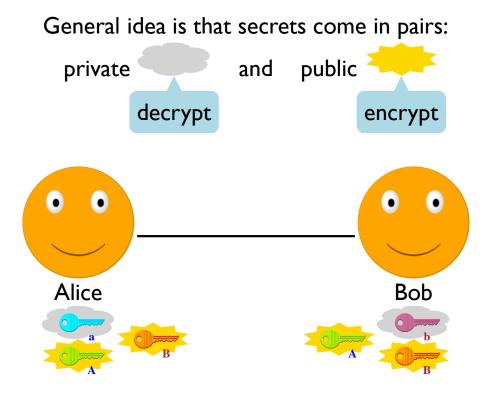

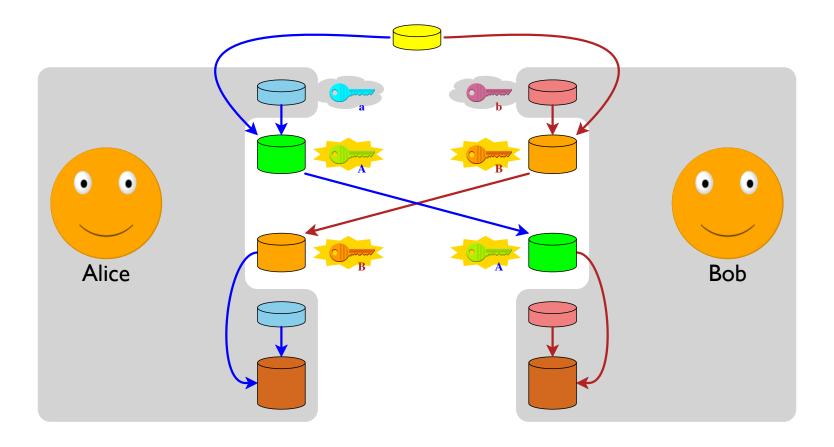

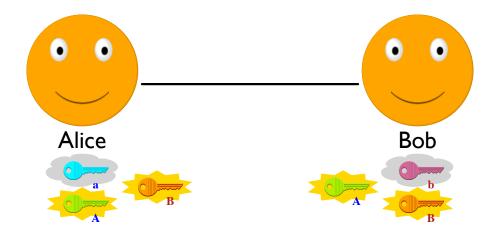

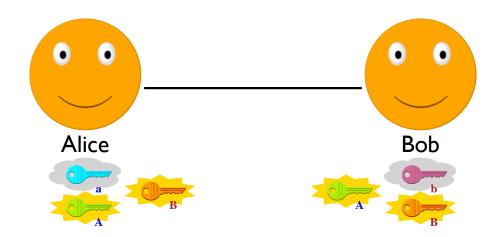

# Diffie-Hellman Key Exchange as Public Key Infrastructure

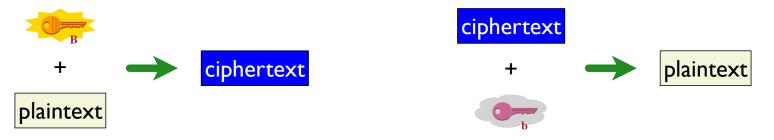

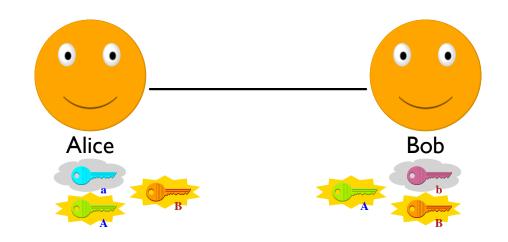

#### **Diffie-Hellman**

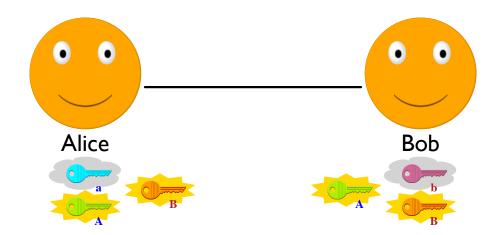

#### **RSA** to Bob

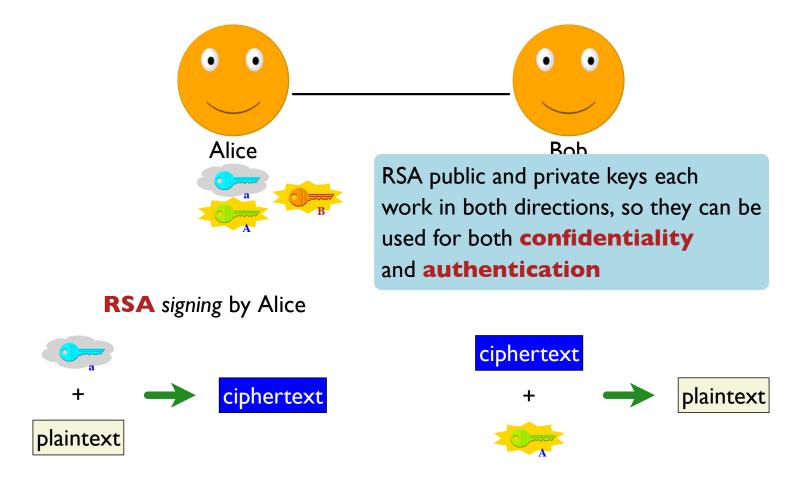

#### **RSA** to Alice

**RSA** signing by Alice

# Alice picks

- ullet p and q as large, random, k-bit prime numbers
- e as relatively prime to  $(p-1) \times (q-1)$

# Alice picks

Something like 1024 to 8192

- p and q as large, random, k-bit prime numbers
- e as relatively prime to  $(p-1) \times (q-1)$

# Alice picks

Easy to generate with high probability due to density of prime numbers and a quick "probably prime" test

- p and q as large, random, k-bit prime numbers
- e as relatively prime to  $(p-1) \times (q-1)$

# Alice picks

- p and q as large, random, k-bit prime numbers
- e as relatively prime to  $(p-1) \times (q-1)$

Even easier: arbitrary number plus a single mod 0 check

# Alice picks

- p and q as large, random, k-bit prime numbers
- e as relatively prime to  $(p-1) \times (q-1)$

Find **d** so that  $(\mathbf{e} \times \mathbf{d}) \mod ((\mathbf{p}-1) \times (\mathbf{q}-1)) = 1$ 

Define  $N = p \times q$ 

### Alice picks

- p and q as large, random, k-bit prime numbers
- e as relatively prime to  $(p-1) \times (q-1)$

Find **d** so that  $(\mathbf{e} \times \mathbf{d}) \mod ((\mathbf{p}-1) \times (\mathbf{q}-1)) = 1$ 

Define  $N = p \times q$ 

Modular inverse using extended Euclidean algorithm

### Alice picks

- p and q as large, random, k-bit prime numbers
- e as relatively prime to  $(p-1) \times (q-1)$

Find **d** so that  $(\mathbf{e} \times \mathbf{d}) \mod ((\mathbf{p}-1) \times (\mathbf{q}-1)) = 1$ 

Define  $N = p \times q$ 

Factoring out p and q is infeasible

#### Alice picks

- p and q as large, random, k-bit prime numbers
- e as relatively prime to  $(p-1) \times (q-1)$

Find **d** so that  $(\mathbf{e} \times \mathbf{d}) \mod ((\mathbf{p}-1) \times (\mathbf{q}-1)) = 1$ 

Define  $N = p \times q$ 

$$\mathbf{a} = \langle \mathbf{d}, \mathbf{N} \rangle$$

$$\mathbf{a} = \langle \mathbf{d}, \mathbf{N} \rangle$$

$$\mathbf{A} = \langle \mathbf{e}, \mathbf{N} \rangle$$

#### Alice picks

- p and q as large, random, k-bit prime numbers
- e as relatively prime to  $(p-1) \times (q-1)$

Find **d** so that 
$$(\mathbf{e} \times \mathbf{d}) \mod ((\mathbf{p}-1) \times (\mathbf{q}-1)) = 1$$

Define 
$$N = p \times q$$

$$\mathbf{a} = \langle \mathbf{d}, \mathbf{N} \rangle$$

$$\mathbf{A} = \langle \mathbf{e}, \mathbf{N} \rangle$$

$$\mathbf{A} = \langle \mathbf{e}, \mathbf{N} \rangle$$

$$\frac{\mathsf{ciphertext}_{\mathsf{i}}^{\mathsf{e}} \bmod \mathbf{N} = \boxed{\mathsf{plaintext}_{\mathsf{i}}}$$

#### Alice picks

- p and q as large, random, k-bit prime numbers
- e as relatively prime to  $(p-1) \times (q-1)$

Find **d** so that  $(\mathbf{e} \times \mathbf{d}) \mod ((\mathbf{p}-1) \times (\mathbf{q}-1)) = 1$ 

Define  $N = p \times q$ 

k-bit chunk of message

$$\mathbf{a} = \langle \mathbf{d}, \mathbf{N} \rangle$$

$$\mathbf{A} = \langle \mathbf{e}, \mathbf{N} \rangle$$

$$\frac{|\mathbf{plaintext}|^{\mathbf{d}} \mod \mathbf{N} = \frac{|\mathbf{ciphertext}|^{\mathbf{d}}}{|\mathbf{ciphertext}|^{\mathbf{d}}}$$

$$\mathbf{A} = \langle \mathbf{e}, \mathbf{N} \rangle$$

$$\frac{\mathsf{ciphertext}_{\mathsf{i}}^{\mathsf{e}} \bmod \mathbf{N} = \boxed{\mathsf{plaintext}_{\mathsf{i}}}$$

# RSA versus a Block Cipher

### Compared to AES

- RSA is 1000x slower
- RSA has 10x larger keys (e.g., 2048 bits vs. 192 bits)
- RSA is more complex

... but RSA requires no initial shared secret

# Using RSA

#### Generate a key pair:

```
openssl genrsa -out private.pem 1024
openssl rsa -pubout -in private.pem > public.pem
```

### Sign a message:

openssl rsautl -sign -inkey private.pem -in a.txt > sig

#### Verify a signed message:

openssl rsautl -verify -pubin -inkey public.pem -in sig

# Summary

Public key cryptography uses public information to bootstrap a private conversation

#### **Diffie-Hellman**

A way to arrive at a shared secret •

Shared can then be used for a stream cipher, for example

Relies on the difficulty of the discrete logarithm problem

#### **RSA**

Published public key enables **confidential** message to owner, **authentication** by owner

Relies on the difficulty of **prime factorization**
